

Understand extension permissions before install.

Permi helps reviewers, builders, and cautious users inspect a Chrome Web Store extension's manifest file without installing the target extension first.

Purpose

Browser extension permissions can be difficult to understand from a store listing alone. Permi gives you the underlying manifest before installing.

Output

Permi saves a formatted manifest.json file through Chrome's downloads flow, using a unique filename based on the target extension ID.

Useful for

- Checking requested permissions and host access.
- Reviewing extension metadata before install.
- Keeping a local manifest copy for audit notes.

Security and privacy posture

C **Strict CSP**
Blocks loads by default, then allows only local assets and Google's CRX hosts.

P **Narrow permissions**
Uses downloads plus host access for Google's CRX update and delivery endpoints.

V **Input validation**
Accepts only Chrome Web Store URLs or valid 32-character extension IDs.

L **Local scripts only**
No remote code, inline scripts, eval, or third-party runtime dependencies.

I **In-memory processing**
Streams CRX bytes with limits, parses locally, and discards package bytes.

N **No tracking or storage**
No analytics, cookies, accounts, ads IDs, or developer-controlled storage.

What it does

Turns a Chrome Web Store URL or extension ID into a readable manifest JSON download.

- 1 Paste a listing**
Use a Chrome Web Store URL or a 32-character extension ID.
- 2 Fetch from Google**
Permi requests the extension package from Google's Chrome update service.
- 3 Extract locally**
The CRX is processed in memory, then only manifest.json is saved.
